A systematic review: Can nasal high flow (NHF) compared with bag valve mask (BVM) use in preoxygenation improve safety in rapid sequence intubation (RSI) in critically ill patients?

Sarah Wei, Sister at MFT Amber Horton, RN at Christie Hospital

Introduction

- The NAP4 project found that 1 in 4 cases of airway complications occurred in ICU or ED.
- NHF was found to potentially improve oxygenation and prolong safe apnoea time in anaesthetic environments.
- Potential benefits of using NHF for preoxygenation is to bypass from face mask to BVM and prolonged oxygenation and preoxygenation during RSI.
- There were no systematic review comparing BVM and NHF for preoxygenation in critically ill patients for RSI.
- This poster was adapted from the primary author's Dissertation for a Critical Care Masters.

Method

- We screened650 studies from12 databases
- 54 studies
 were assessed
 for eligibility and
 4 randomised
 controlled trial
 (RCTs) and 1
 non-RCT were
 included in the
 review. 2 studies
 are still ongoing.
- The 5 studies were assessed for risk of bias.

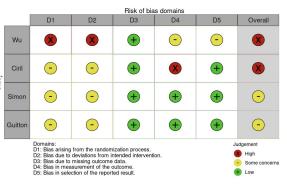

FIGURE 1: RISK OF BIAS VISUALISATION FOR RCTS

FIGURE 2: RISK OF BIAS VISUALISATION FOR NON-RANDOMISED STUDIES

The overall Risk of Bias was High.

Results

- The 4 RCTs (n=417) and 1 non-RCTs (n=319) had mixed results in supporting the use of NHF in preoxygenation.
- When all the studies are included, the lowest % saturation (primary outcome) was statistically significant with a standard mean difference of 0.26 (SMD)(p-0.01).
- However, when the <u>2 RCTs that are</u>
 high risk of bias are removed, there are
 no statistically significant differences
 between the trials
 with a SMD of 0.14
 (p=0.29).
- The overall GRADE is low certainty.

Conclusions & Key Points

- The primary finding is that <u>there is low certainty that NHF does not improve</u> <u>safety more than BVM when used in preoxygenation for RSI in hypoxic</u> <u>patients</u> when examining the lowest % SpO2 during intubation procedure.
- NHF benefits may not be helpful for critically ill patients with shunting because they desaturate rapidly and have reduced oxygen storage.
- In addition, the studies conducted in anaesthetic environments were more ideal for preoxygenation with more optimum conditions compared to ICU.
- Two trials are still ongoing so data may change. Further research with large, low risk of bias RCTs are needed to be conducted.
